Program constructs

Selection constructs - provide alternative paths by using statements like If and Switch.
Iteration constructs - let you repeat blocks of code. The For loop iterates a fixed number of times. A While loop iterates a variable number of times.
Sequence constructs - control the flow of control when a program executes. Normally a program executes one line then goes on to the next line. You can jump to different line with keywords like Goto, Continue, Break. (Avoid the use of Goto statements because it can result in "spagetti" code.) When you call a method, flow logic jumps to the code in the method and then returns to the calling programming.

Selection constructs
There are various way of making decisions in code:

- if { } statement
- if { } else { } statement
- shorthand if-then-else syntax Expr1 ? Expr2 : Expr3
- switch statement

Iteration (code loops)
There are several ways to loop through a block of code:

- for loop
- while loop
- do ... while loop
- foreach loop (for iterating through collections)
